Client Goals & Audience

- **Client Goal**: Promote a neighborhood bakery and encourage pre-orders and inquiries
- **Target Audience**: Local customers, commuters, families, and event planners
- **Design Choice**: Hours, location, and a direct pre-order link right on the Home page
- **Speaker Notes:**

My design choice was to put the bakery's hours, address, and a direct link to the pre-order form on the Home page instead of only on the Contact page. The main thing customers come to do is find out when the bakery is open and place an order. Commuters checking on their phone before work can see the hours and that we are closed Mondays without clicking through other pages. Event planners and families who want to order ahead can tap one link and go straight to the pre-order form, which supports the client's goal of getting more pre-orders and inquiries.

Site Structure & Content

- **Pages Included**: Home, Our Products, About Our Bakery, Contact and Pre-Orders
- **Navigation**: The same menu bar sits at the top of every page, and the current page is underlined
- **Structure Decision**: One clear H1 per page, with H2 headings that break each page into short sections

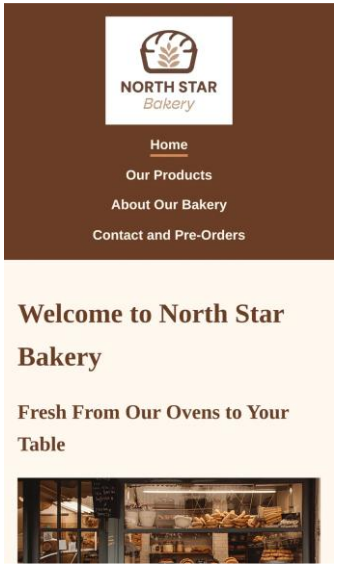

Speaker Notes:

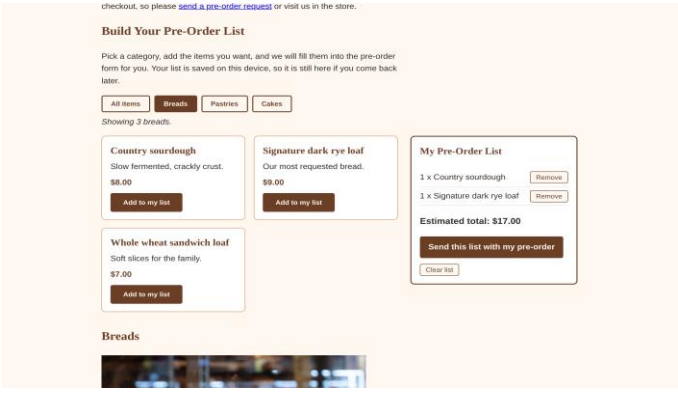

- Every page shares the same header and menu, and the current page is underlined, as shown in the screenshot, so visitors always know where they are. Each page has one main heading with short sections below it, which makes the site easy to scan on a phone or with a screen reader.

Visual Design System

- **Color**: Warm brown, cream, and peach that match the logo and feel handmade
- **Typography**: Georgia for headings, Arial for body text, with high contrast for easy reading
- **Layout**: Mobile-first; the menu stacks on phones and sits in a row on desktop
- **Speaker Notes:**

  I chose dark brown text on a cream background because it matches the bakery's warm, handmade feel and is easy to read. Headings use Georgia and body text uses Arial, so titles stand out clearly from content. On phones the menu stacks into large tap targets, so customers can reach any page with one thumb.

Interactive Feature

- **Feature:** A "Build Your Pre-Order List" tool on the Products page
- **User Action:** Click a category (Breads, Pastries, Cakes), then click "Add to my list"
- **Result:** The product cards filter instantly, and the list updates with quantities and an estimated total.

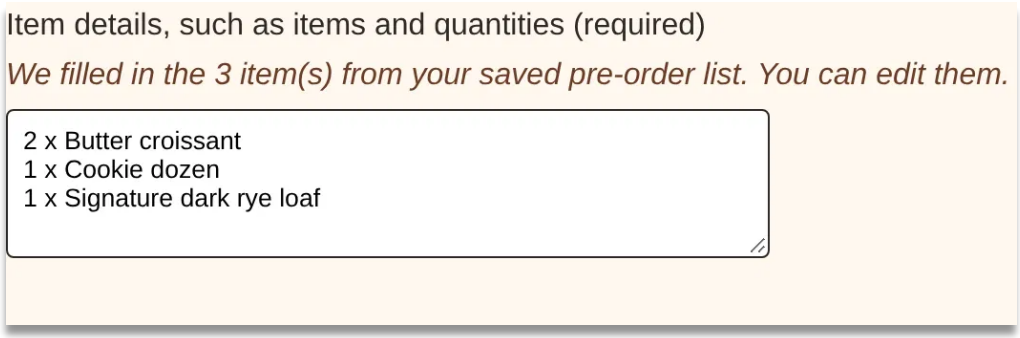

Speaker Notes:

Before this feature, customers had to remember what they wanted and type it all into the order form. Now they can browse by category, tap to add items, and see a running total, as shown in the screenshot. When they click "Send this list with my pre-order," their items are already filled into the form, which makes ordering faster for busy commuters and event planners.

Data Storage

- **Storage Type:** local Storage
- **What is Stored:** The customer's pre-order list (each item and its quantity)
- **When:** Every time an item is added or removed; it loads again when the Products or Contact page opens

Speaker Notes:

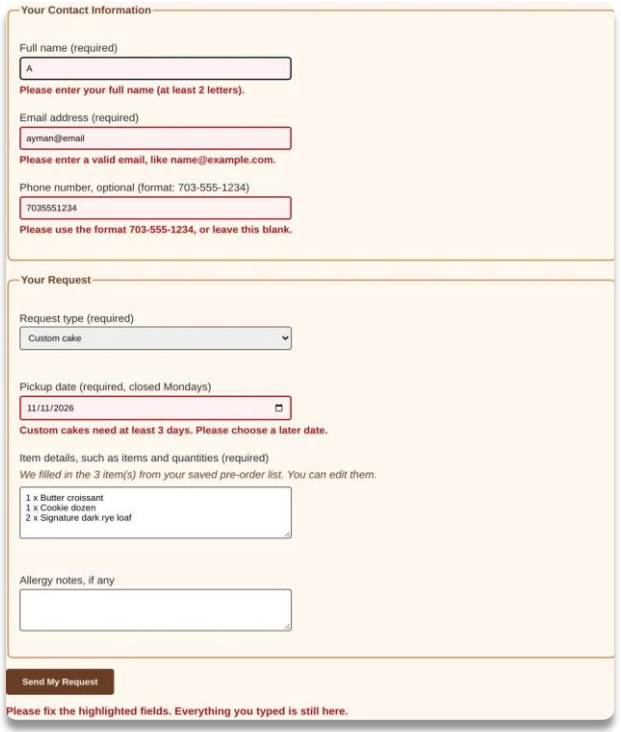

Saving the list in local Storage means customers do not lose their order if they refresh, close the tab, or come back later. When they open the Contact page, their saved items are filled into the form automatically, as shown in the screenshot, so they never have to retype their order.

Accessibility

- **Accessibility Features:** Descriptive alt text on every image, a visible label for every form field, and high-contrast brown on cream colors
- **Focus Feature:** Form error messages appear in text right under each field and are read aloud by screen readers

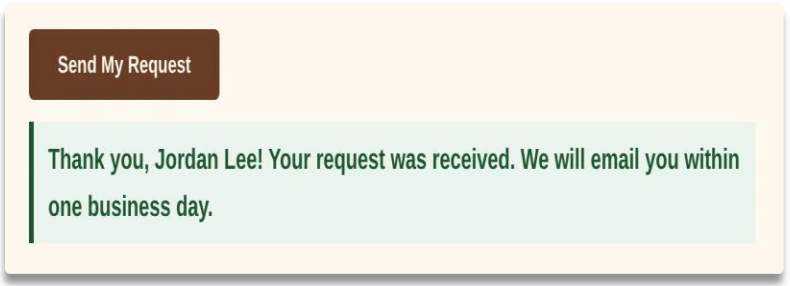

Speaker Notes:

Each error message is written in plain words and placed directly under the field it belongs to, not shown only as a red border. The messages are linked to their fields and announced by screen readers, so blind and low-vision users hear exactly what to fix. This also helps everyone else, including older customers and people on small phone screens, because the fix is clear without guessing.

Self-Evaluation

- **Strength:** The pre-order flow is fast and connected from browsing to sending
- **Evidence:** Items added on the Products page are filled into the Contact form automatically, and a clear confirmation appears after sending
- **User Impact:** Customers order in a few clicks without retyping, which supports the bakery's goal of more pre-orders

Speaker Notes:

My strongest part is how the Products page and the Contact page work together. A customer can build a list, tap "Send this list with my pre-order," and arrive at a form that is already filled in. After sending, a clear green confirmation tells them it worked, so they are never left wondering if their order went through.

Process Reflection

- **Planning**: Early on I mapped which page each photo, the audio, and the form would go on
- **Change**: The pre-order form started as plain HTML; I added a list builder that fills it in for the customer
- **Why**: Typing a whole order from memory was slow, especially on a phone
- **Speaker Notes:**

  In my first version, customers had to type every item into the Item details box by hand. I changed this so they can build their list on the Products page and have it filled into the form automatically. This made ordering faster, reduced spelling mistakes in item names, and made the site feel more like a real bakery ordering tool.

Challenges & Lessons Learned

- **Challenge:** The browser showed its own pop-up warnings instead of my custom error messages, and the form shifted when errors cleared
- **Solution:** Added novalidate to the form so JavaScript handles validation, and gave error messages a fixed height
- **Lesson:** Test every interaction in the browser, not just whether the code runs

Speaker Notes:

At first my form looked fine in the code, but when I tested it the browser's default pop-ups covered my own messages, and fixing a field made the page jump so the button moved before I could click it. I only found these problems by actually using the form. Next time I will test each feature step by step in the browser as I build it, instead of waiting until the end.
